

Test Document for PDF Loader

This is a test document created to verify the PDF loading functionality in our RAG application. The document contains multiple paragraphs to test how well the PDF loader extracts text content from different parts of the document. This is important for maintaining compatibility with the existing text processing pipeline. Key features to test: - Text extraction from multiple pages - Handling of different text formatting - Compatibility with the existing TextFileLoader interface - Integration with the CharacterTextSplitter The goal is to ensure that PDF files can be processed in the same way as text files, maintaining the same output format for the vector database and RAG pipeline.

Additional content for testing purposes. This paragraph contains information about the RAG (Retrieval Augmented Generation) system and how it processes different types of documents including text files and now PDF files. The system should be able to: 1. Load PDF documents 2. Extract text content 3. Split the content into chunks 4. Generate embeddings 5. Store in the vector database 6. Enable semantic search and retrieval This ensures that users can work with both text and PDF documents seamlessly in their RAG applications.
